

Pre-test Knowledge Questionnaire

The following questions aim to assess your knowledge of software security and security patterns after your participation in the teaching and learning activity using a traditional lecture. To do so, please follow the recommendations below:

- Answer based exclusively on your acquired knowledge, without consulting materials, colleagues, or other external sources.
- Try to answer as many questions correctly as possible. However, if you do not know the answer, select the option “I do not know” instead of choosing a random alternative.

Notes: Before submitting the form, please review your answers to ensure that you have not accidentally left any fields blank.

1. What is your name? (Required)

2. What is your email address? (Required)

3. How does an Injection attack work? (Required)

() In an injection attack, an attacker inserts malicious commands into a vulnerable system. A strong and complex password can prevent this, as it adds an extra layer of security and makes injections harder to execute.

() An injection attack occurs when a system allows malicious data to be injected into unvalidated inputs, such as forms. Systems that properly validate and sanitize inputs can prevent these attacks, protecting data and system integrity.

() Injection attacks can only be prevented by antivirus tools that detect malicious code and automatically block any attempt to inject data into the system.

() An injection attack can be prevented by creating obfuscated source code, which makes scripts difficult to read and prevents any attempt to inject commands into the system.

() I do not know.

4. What are the consequences of a cryptographic failure in a web application? (Required)

() Leakage of sensitive data, such as passwords and personal information.

() Improved system performance due to the use of faster algorithms.

() Increased user trust due to effective cryptography.

() A security flaw that can be fixed without compromising data.

() I do not know.

5. Correctly match the vulnerabilities with their corresponding security patterns by choosing the correct alternative: (Required)

Vulnerabilities	Security Patterns
A. SQL Injection	1. Input Validation
B. Cross-Site Scripting (XSS)	2. Output Encoding
C. Broken Authentication	3. Multi-Factor Authentication
D. Insecure Direct Object Reference	4. Access Control Enforcement

- () 1 → A, 2 → B, 3 → C, 4 → D
- () 1 → B, 2 → A, 3 → D, 4 → C
- () 1 → C, 2 → D, 3 → B, 4 → A
- () 1 → D, 2 → C, 3 → A, 4 → B
- () I do not know.

6. How can an Access Control Violation/Broken Access Control attack be prevented? (Required)

- () Allow anyone to access the system without restrictions.
- () Use only URLs to determine who can access what in the system.
- () Allow users to modify their own access permissions.
- () Implement Least Privilege policies and access control mechanisms.
- () I do not know.

7. Regarding SQL injection and database security: A web system stores user credentials in a database. Which of the following approaches may still be vulnerable to SQL injection, even if it appears secure? (Required)

- () Use of parameterized queries (prepared statements) with input type checking.
- () Validation of user input only on the frontend before sending data to the server.
- () Use of ORM (Object-Relational Mapping) with native support for input escaping.
- () Use of stored procedures that do not concatenate user inputs directly into SQL commands.
- () I do not know.

8. Why are logging and activity monitoring essential for system security? (Required)

- () They allow the identification of suspicious activities and rapid incident response.
- () They completely eliminate the need to apply security patches.
- () They replace the need for multi-factor authentication (MFA).
- () They are useful only for fiscal auditing and do not affect security.
- () I do not know.

9. Regarding cryptographic failures and secure credential storage: Which of the following approaches represents the best security practice for password storage? (Required)

- () Store passwords encrypted with AES-256 using a fixed key embedded in the

source code.

- () Use a strong hashing algorithm, such as bcrypt, Argon2, or PBKDF2, with a unique salt for each password.
- () Store passwords in plaintext, protected only by a firewall and restricted database access.
- () Use the same encryption key across multiple systems.
- () Create a custom password hashing algorithm, since known solutions may be compromised.
- () I do not know.

10. Regarding broken access control: Which of the following configurations can lead to a broken access control vulnerability in a web system? (Required)

- () Implementing access control only on the frontend without backend enforcement.
- () Using JSON Web Tokens (JWT) with a short expiration time.
- () Applying the principle of least privilege to all administrative functions.
- () Implementing access control lists (ACLs) to define role-based permissions.
- () I do not know.

11. After an attack on an e-commerce platform in which customer payment data were altered by an attacker, what would be the best practice to prevent data integrity failures? (Required)

- () Do not encrypt payment data so employees can easily access them.
- () Implement strong encryption for sensitive data (e.g., credit card numbers) and use multi-factor authentication for administrative access.
- () Ignore data integrity validation when receiving data from third parties, such as payment processors.
- () Allow customers to modify their own transactions directly in the system without additional controls.
- () I do not know.

12. In a company, a version control system was compromised due to a lack of code authenticity verification. What could be done to improve software integrity and protect against unauthorized modifications? (Required)

- () Allow any employee to modify the source code without control or approval.
- () Implement digital signatures on source code and use a version control system that records all changes with strict auditing.
- () Avoid applying patches or updates to prevent integrity risks.
- () Store source code on public servers to ensure easy and fast access.
- () I do not know.

13. On an e-commerce website, a user changes the account ID in the URL from “12345” to “12346” and accesses another user’s data. Which security vulnerability is occurring? (Required)

- () SQL Injection
- () XSS
- () Broken Access Control
- () CSRF
- () I do not know.

14. An attacker exploits a flaw in a software system by altering source code or stored data to modify system behavior, compromising its accuracy and reliability. Which vulnerability is being exploited in this scenario? (Required)

- SQL Injection
- Cross-Site Scripting (XSS)
- Code or data tampering (exploiting software integrity)
- Phishing
- I do not know.
